Anotácia:

Proximity-induced effects in graphene-based van der Waals heterostructures have been shown to provide an efficient way to tune graphene's low-energy electronic states [1]. Transition metal dichalcogenide 1T-TaS₂ exhibits a variety of periodic lattice distortions, triggering a stable low-temperature periodic charge density wave with a David star pattern and magnetic ground state in the monolayer limit. In the talk, we will discuss proximity-induced effects such as spin-orbit coupling and exchange interaction in graphene on monolayer 1T-TaS₂ using density functional theory and tight-binding modeling [2]. Using the effective tight-binding model, the charge to spin conversion efficiency using the linear Kubo response approach and the self-induced torque within the non-equilibrium Green's function transport will be presented.
